ABSTRACT

A new class of solutions for Einstein's field equations representing a static spherically symmetric anisotropic distribution of matter is obtained on the background of pseudo-spheroidal spacetime. We have prescribed the bounds of the model parameters k and p_0 on the basis of the elementary criteria for physical acceptability, viz., regularity, stability and energy conditions. By taking the values of model parameters from the prescribed bounds, we have shown that our model is compatible with the observational data of a wide variety of compact stars like 4U 1820-30, PSR J1903+327, 4U 1608-52, Vela X-1, PSR J1614-2230, SMC X-4 and Cen X-3.

Subject headings: General relativity; Exact solutions; Relativistic compact stars.

1. Introduction

The study of compact objects in agreement with observational data has received wide attention among researchers. A number of superdense star models, compatible with observational data, have appeared in literature in the recent past (Murad (2013a), Murad and Saba (2013b,c, 2014a), Maurya *et al.* (2015) & Sharma and Ratanpal (2013)). If spacetime admitting compact star models possess a definite three-space geometry, then it is a mathematically interesting problem also. The spheroidal spacetimes studied by Vaidya and Tikekar (1982), Tikekar (1990) and the paraboloidal spacetime studied by Finch and Skea (1989), Tikekar and Jotania (2005), Sharma and Ratanpal (2013) are examples of spacetimes with definite 3-space geometry. The superdense star models developed by Tikekar and Thomas (1998) has pseudo-spheroidal geometry. A number of researchers used this spacetime for developing physically viable models of compact stars under different assumptions on the physical content.

Theoretical investigations of Ruderman (1972) and Canuto (1974) suggest that matter may not isotropic in ultra high density regime. After the publication of the work of Bowers and Liang (1974), there has been a large number of models devoted to the study of anisotropic distribution of matter. Maharaj and Maartens (1989) developed an anisotropic model with uniform density and Gokhroo and Mehra (1972) gave a more realistic anisotropic model with non-uniform density. Tikekar (1999); Tikekar and Thomas (2005), Thomas *et al.* (2005) developed superdense anisotropic distributions on pseudo-spheroidal spacetimes. Thomas and Ratanpal (2007) studied non-adiabatic gravitational collapse of anisotropic distribution of matter accompanied by radial heat flux. Dev and Gleiser (2002, 2003, 2004) have studied the impact of anisotropy on the stability of stellar configuration. Anisotropic distributions of matter incorporating linear equation of state have been studied by Sharma and Maharaj (2007), & Thirukkanesh and Maharaj (2008). Komathiraj and Maharaj (2007) have studied charged distribution using linear equation

of state. Sunzu *et al.* (2014) studied charged anisotropic quark stars using linear equation of state. Anisotropic distributions of matter incorporating quadratic equation of state have been given by Feroze and Siddiqui (2011) & Maharaj and Takisa (2012). Varela *et al.* (2010) used linear and non-linear equations of state for describing charged anisotropic distributions of matter. Paul *et al.* (2011) have shown, in the MIT bag model of quark stars, that anisotropy can affect the bag constant. Polytropic equations of state has been used by Thirukkanesh and Ragel (2012) & Maharaj and Takisa (2013b). Malaver (2013a,b, 2014) and Thirukkanesh and Ragel (2014) have used modified Van der Waals equation of state for describing anisotropic charged compact stars.

Recently Pandya *et al.* (2015) have developed anisotropic models of compact stars compatible with observational data by generalizing Finch and Skea (1989) ansatz. The anisotropic stellar model given by Sharma and Ratanpal (2013) is a subclass of the model of Pandya *et al.* (2015). This model accommodates the observational data of a variety of compact objects recently studied by researchers. In the present article, we have obtained a new class of anisotropic stellar model of compact objects on the background of pseudo-spheroidal spacetimes. The physical parameter p_0 and geometric parameter k appearing in the model are restricted as a result of various physical acceptability conditions imposed on the model. Another geometric parameters R of the model plays the role of the radius of the spherical distribution of matter. It is found that our model yields values of different physical quantities that are in good agreement with the most recently available observational data of compact objects (Gangopadhyay *et al.* (2013)) like 4U 1820-30, PSR J1903+327, 4U 1608-52, Vela X-1, PSR J1614-2230, SMC X-4 and Cen X-3.

We have organized the paper as follows: In section 2, we have solved the field equations and obtained restrictions on the model parameters using various physical requirements and energy conditions. The bounds for the model parameters k and p_0 are obtained in section 3. In section

4, we have shown that our model is compatible with recent observational data of a number of compact objects (Gangopadhyay *et al.* (2013)). The main results obtained in the present work is discussed in section 5.

2. Spacetime metric

A three-pseudo spheroid immersed in four-dimensional Euclidean space has the Cartesian equation

$$\frac{u^2}{b^2} - \frac{x^2+y^2+z^2}{R^2} = 1.$$

The sections $u = constant$ are spheres of real or imaginary radius according as $u^2 > b^2$ or $u^2 < b^2$, while the sections $x = const$, $y = const$, and $z = const$ are respectively, hyperboloids of two sheets.

On taking the parametrization

$$\begin{aligned} x &= Rsinh\lambda sin\theta cos\phi \\ y &= Rsinh\lambda sin\theta sin\phi \\ z &= Rsinh\lambda cos\theta \\ u &= bcosh\lambda \end{aligned} \tag{1}$$

the Euclidean metric

$$d\sigma^2 = dx^2 + dy^2 + dz^2 + du^2$$

takes the form

$$d\sigma^2 = \frac{1+k\frac{r^2}{R^2}}{1+\frac{r^2}{R^2}} dr^2 + r^2 d\theta^2 + r^2 sin^2\theta d\phi^2 \tag{2}$$

where $k = 1 + \frac{b^2}{R^2}$ and $r = Rsinh\lambda$. The metric (2) is regular for all points with $k > 1$ and call pseudo-spheroidal metric (Tikekar and Thomas (1998)).

We take the interior metric describing the anisotropic matter distribution in the form

$$ds^2 = e^{\nu(r)}dt^2 - \frac{1+k\frac{r^2}{R^2}}{1+\frac{r^2}{R^2}}dr^2 - r^2d\theta^2 - r^2sin^2\theta d\phi^2, \tag{3}$$

where, k, R are geometric parameters and $k > 1$. This spacetime, generally known as pseudo-spheroidal spacetime, has been studied by many researchers (Tikekar and Thomas (1998); Tikekar (1999); Tikekar and Thomas (2005); Thomas *et al.* (2005); Thomas and Ratanpal (2007); Paul *et al.* (2011); Chattopadhyay and Paul (2010); Chattopadhyay *et al.* (2012)).

Following Maharaj and Maartens (1989), we write the energy-momentum tensor for anisotropic matter distribution in the form

$$T_{ij} = (\rho + p)\,u_iu_j - pg_{ij} + \pi_{ij}, \tag{4}$$

where, ρ, p and u_i denote the proper density, fluid pressure and unit four-velocity of the fluid, respectively.

The anisotropic stress-tensor π_{ij} is given by

$$\pi_{ij} = \sqrt{3}S\left[C_iC_j - \frac{1}{3}(u_iu_j - g_{ij})\right], \tag{5}$$

where, $C^i = (0, -e^{-\lambda/2}, 0, 0)$ is a radial vector and $S = S(r)$ denotes the magnitude of the anisotropic stress.

The non-vanishing components of the energy-momentum tensor are given by

$$T_0^0 = \rho, \quad T_1^1 = -\left(p + \frac{2S}{\sqrt{3}}\right), \quad T_2^2 = T_3^3 = -\left(p - \frac{S}{\sqrt{3}}\right). \tag{6}$$

Hence the radial and transverse pressures are given by

$$p_r = -T_1^1 = \left(p + \frac{2S}{\sqrt{3}}\right), \tag{7}$$

$$p_\perp = -T_2^2 = \left(p - \frac{S}{\sqrt{3}}\right). \tag{8}$$

Then the magnitude of the anisotropic stress has the form

$$S = \frac{p_r - p_\perp}{\sqrt{3}}. \tag{9}$$

The physical and geometric variables, related through Einstein's field equations

$$R_{ij} - \frac{1}{2}Rg_{ij} = 8\pi T_{ij}, \tag{10}$$

are to be determined from the following set of three equations:

$$8\pi\rho = \frac{1-e^{-\lambda}}{r^2} + \frac{e^{-\lambda}\lambda'}{r}, \tag{11}$$

$$8\pi p_r = \frac{e^{-\lambda}-1}{r^2} - \frac{e^{-\lambda}\nu'}{r}, \tag{12}$$

$$8\pi p_\perp = e^{-\lambda}\left[\frac{\nu''}{2} + \frac{\nu'^2}{4} - \frac{\nu'\lambda'}{4} + \frac{\nu'-\lambda'}{2r}\right], \tag{13}$$

where a prime denotes a differentiation with respect to r. The equations (11) – (13) can be couched in the form

$$e^{-\lambda} = 1 - \frac{2m}{r}, \tag{14}$$

$$\left(1 - \frac{2m}{r}\right)\nu' = 8\pi p_r r + \frac{2m}{r^2}, \tag{15}$$

$$-\frac{4}{r}(8\pi\sqrt{3}S) = (8\pi\rho + 8\pi p_r)\nu' + 2(8\pi p_r'), \tag{16}$$

where

$$m(r) = 4\pi\int_0^r u^2\rho(u)du. \tag{17}$$

The energy-density ρ and the mass m within the radius r have expressions

$$8\pi\rho = \frac{k-1}{R^2}\frac{\left(3+k\frac{r^2}{R^2}\right)}{\left(1+k\frac{r^2}{R^2}\right)^2}, \tag{18}$$

$$m(r) = \frac{R}{2}\frac{(k-1)\frac{r^2}{R^2}}{1+\frac{kr^2}{R^2}}. \tag{19}$$

It can be easily obtained from equation (18) that

$$8\pi\rho' = -\frac{2k(k-1)r}{R^4}\frac{\left(5+k\frac{r^2}{R^2}\right)}{\left(1+k\frac{r^2}{R^2}\right)^3} < 0, \tag{20}$$

indicating that the density decreases radially outward.

In order to obtain the metric potential ν, we assume an expression for p_r in equation (15), in the form

$$8\pi p_r = \frac{p_0}{R^2}\frac{\left(1-\frac{r^2}{R^2}\right)\left(1+\frac{r^2}{R^2}\right)}{\left(1+k\frac{r^2}{R^2}\right)^2}. \tag{21}$$

The radial pressure in the present form vanishes at $r = R$ and takes the value $\frac{p_0}{R^2}$ at the centre $r = 0$. It is non-negative for all values of r in the range $0 \leq r \leq R$. Further, on differentiating equation (21) with respect to r, we get

$$8\pi p_r' = -\frac{4p_0 r\left(k+\frac{r^2}{R^2}\right)}{R^4\left(1+k\frac{r^2}{R^2}\right)^3} < 0, \tag{22}$$

indicating that the pressure p_r decreases radially outward. Since $p_r(r = R) = 0$, the geometric parameter R takes the role of the boundary radius of the distribution. With this choice of p_r, equation (15) can be integrated to obtain ν in the form

$$e^{\nu} = A\left(1+k\frac{r^2}{R^2}\right)^{\frac{p_0(k+1)}{2k^2}}\left(1+\frac{r^2}{R^2}\right)^{\frac{k-1}{2}} exp\left\{\frac{-p_0}{2k^2}\left(1+k\frac{r^2}{R^2}\right)\right\} \tag{23}$$

where A is a constant of integration.

Therefore, the spacetime metric takes the explicit form

$$ds^2 = A\left(1+k\frac{r^2}{R^2}\right)^{\frac{p_0(k+1)}{2k^2}}\left(1+\frac{r^2}{R^2}\right)^{\frac{k-1}{2}} \times exp\left\{\frac{-p_0}{2k^2}\left(1+k\frac{r^2}{R^2}\right)\right\}dt^2 - \frac{1+k\frac{r^2}{R^2}}{1+\frac{r^2}{R^2}}dr^2 - r^2d\theta^2 - r^2sin^2\theta d\phi^2. \tag{24}$$

The constant of integration A can be obtained by matching the interior spacetime metric (3) with the Schwarzschild exterior metric

$$ds^2 = \left(1-\frac{2m}{r}\right)dt^2 - \left(1-\frac{2m}{r}\right)^{-1}dr^2 - r^2d\theta^2 - r^2sin^2\theta d\phi^2 \tag{25}$$

across the boundary $r = R$. This gives

$$R = \frac{2M(k+1)}{(k-1)}, \tag{26}$$

and

$$A = \frac{2}{k+1}\left(\frac{e}{k+1}\right)^{\frac{(k+1)p_0}{2k^2}} 2^{-\left(\frac{k-1}{2}\right)}. \tag{27}$$

The expression for anisotropy is now readily available by substituting for p_r, p_r' and ν' in the equation (16).

$$8\pi\sqrt{3}S = \frac{r^2}{R^2}\left(\frac{2p_0\left(k+\frac{r^2}{R^2}\right)}{R^2\left(1+\frac{kr^2}{R^2}\right)^3} - \frac{B(r)C(r)}{R^2\left(1+k\frac{r^2}{R^2}\right)}\right), \tag{28}$$

where

$$B(r) = \left[\frac{p_0\left(1-\frac{r^2}{R^2}\right)}{4\left(1+\frac{kr^2}{R^2}\right)^4} + \frac{k-1}{4\left(1+\frac{r^2}{R^2}\right)}\right], \tag{29}$$

$$C(r) = \left[(k-1)\left(3+k\frac{r^2}{R^2}\right) + p_0\left(1-\frac{r^4}{R^4}\right)\right]. \tag{30}$$

It is easy to see that S vanishes at origin $r = 0$, which is a desired requirement for anisotropic distributions (Murad (2013a), Murad and Saba (2013b,c, 2014a) & Bowers and Liang (1974)). The expression for transverse pressure

$$8\pi p_\perp = 8\pi p_r - 8\pi\sqrt{3}S \tag{31}$$

can be obtained using equations (21) and (28).

Moreover, the condition $p_\perp \geq 0$ will lead to the following inequality at $r = R$

$$p_0 \leq \frac{1}{16}(k-1)^2(k+3), \tag{32}$$

whereas at $r = 0$, the condition is evidently satisfied.

The expressions for $\frac{dp_r}{d\rho}$ and $\frac{dp_\perp}{d\rho}$ are given by

$$\frac{dp_r}{d\rho} = \frac{2p_0}{k(k-1)} \frac{\left(k + \frac{r^2}{R^2}\right)}{\left(5 + k\frac{r^2}{R^2}\right)}, \tag{33}$$

$$\frac{dp_\perp}{d\rho} = \frac{dp_r}{d\rho} - \sqrt{3}\frac{dS}{d\rho}. \tag{34}$$

The conditions $0 \leq \frac{dp_r}{d\rho} \leq 1$ and $0 \leq \frac{dp_\perp}{d\rho} \leq 1$ at $r = 0$, respectively, give the inequalities

$$0 \leq p_0 \leq \frac{5}{2}(k-1), \tag{35}$$

and

$$0 \leq p_0 \leq \frac{k(k-1)(k+5)}{2(k+1)}. \tag{36}$$

Similarly the above conditions at $r = R$, respectively, give

$$2(3k+1) - \sqrt{33k^2+30k+1} \leq p_0 \leq 2(3k+1) - \sqrt{13k^2+50k+1}, \tag{37}$$

and

$$0 < p_0 \leq \frac{-k^4+12k^3+78k^2-92k+3}{8k^2-24k+80}. \tag{38}$$

The adiabatic index

$$\Gamma = \frac{\rho + p_r}{p_r}\frac{dp_r}{d\rho} \tag{39}$$

has the explicit expression

$$\Gamma = \frac{2\left(k + \frac{r^2}{R^2}\right)C(r)}{k(k-1)\left(5 + k\frac{r^2}{R^2}\right)\left(1 - \frac{r^4}{R^4}\right)}. \tag{40}$$

The necessary condition for the model to represent a relativistic star is that $\Gamma > \frac{4}{3}$ throughout the star. $\Gamma > \frac{4}{3}$ at $r = 0$ impose a condition on p_0, viz.,

$$p_0 > \frac{k-1}{3}. \tag{41}$$

The strong energy condition $\rho - p_r - 2p_\perp \geq 0$ at $r = 0$ and $r = R$, respectively, give the following two inequalities

$$p_0 \leq k - 1 \tag{42}$$

and

$$p_0 \geq \frac{(k+3)(k-1)(k-5)}{16} \tag{43}$$

In order to obtain a valid range for the parameters p_0 and k, we have to consider the inequalities (35) – (38) and (40) – (43) simultaneously.

3. Bounds for Model Parameters

The pseudo-spheroidal space-time model developed for anisotropic matter distribution contains a physical parameter p_0 related to the central pressure and two geometric parameters, viz., R and k. Since $p_r(r = R) = 0$, the free parameter R represents the radius of the distribution. The bounds for the other two parameters p_0 and k are to be determined by the following requirements a physically acceptable model is expected to satisfy in its region of validity, $0 \leq r \leq R$.

1) $\rho(r) \geq 0, \;\; p_r(r) \geq 0, \;\; p_\perp(r) \geq 0;$

2) $\rho(r) - p_r(r) - 2p_\perp(r) \geq 0$;

3) $\frac{d\rho(r)}{dr} < 0, \;\; \frac{dp_r(r)}{dr} < 0;$

4) $0 \leq \frac{dp_r}{d\rho} \leq 1, \;\; 0 \leq \frac{dp_\perp}{d\rho} \leq 1$;

5) The adiabatic index $\Gamma(r) > \frac{4}{3}$.

The conditions $\rho(r) \geq 0, p_r(r) \geq 0, \frac{d\rho(r)}{dr} < 0, \frac{dp_r(r)}{dr} < 0$ are automatically satisfied by equations (18), (21), (20), (22).

We have displayed in Table 1 the bounds on p_0 in terms of the parameter k at the centre and on the boundary.

Table 1: Bounds for p_0.

Physical requirements	**at** $r = 0$	**at** $r = R$
$\rho - p_r - 2p_\perp \geq 0$	$p_0 \leq k-1$	$p_0 \geq \frac{(k+3)(k-1)(k-5)}{16}$
$0 \leq \frac{dp_r}{d\rho} \leq 1$	$0 \leq p_0 \leq \frac{5}{2}(k-1)$	$2(3k+1) - \sqrt{(33k^2+30k+1)} \leq p_0$ $\leq 2(3k+1) - \sqrt{(13k^2+50k+1)}$
$0 \leq \frac{dp_\perp}{d\rho} \leq 1$	$0 \leq p_0 \leq \frac{k(k-1)(k+5)}{2(k+1)}$	$0 \leq p_0 \leq \frac{-k^4+12k^3+78k^2-92k+3}{8k^2-24k+80}$
$\Gamma(r) \geq \frac{4}{3}$	$p_0 > \frac{k-1}{3}$	Automatically satisfied

We have displayed the numerical values of the lower and upper bounds of p_0 for different values of $k > 1$ in Table 2. We have considered the maximum of all lower limits of p_0 and minimum of all its upper limits. The admissible values of k are those for which minimum of upper limit minus maximum of lower limit is positive. This condition restricts the values of k in the range $(2.05, 5.69)$. It is further observed that for $2.05 < k \leq 3.47$, $3.47 \leq k \leq 5.24$, and $5.24 \leq k < 5.69$, p_0 satisfies, respectively, the inequalities $\frac{k-1}{3} < p_0 \leq \frac{(k+3)(k-1)^2}{16}$, $\frac{k-1}{3} \leq p_0 \leq k-1$ and

$\frac{1}{6}(k+3)(k-1)(k-5) \leq p_0 < k-1$. The shaded region in Figure 1 gives the permissible values of k and p_0. Any values of k and p_0 outside this region may violate one or other of the physical requirements of the model.

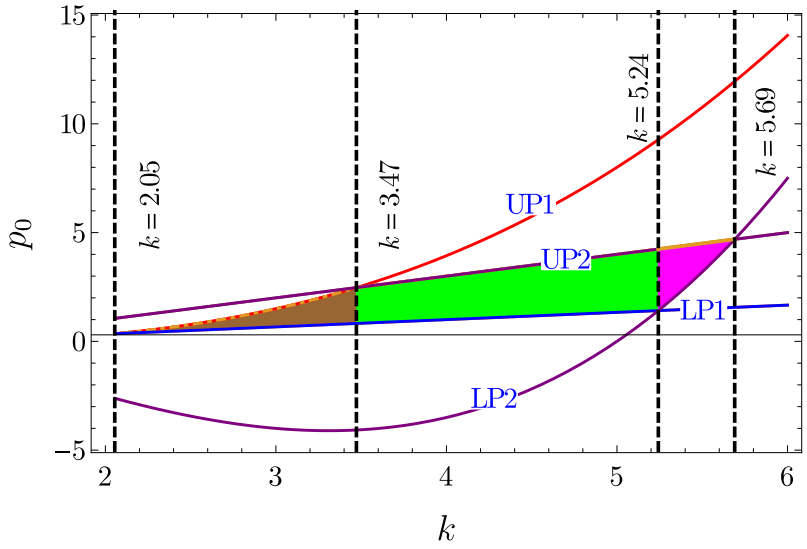

Fig. 1.— Permissible values of p_0 and k

Table 2: Permissible values of k and p_0.

Here, $LP1 = \frac{k-1}{3}$, $LP2 = \frac{(k+3)(k-1)(k-5)}{6}$, $LP3 = 2(3k+1) - \sqrt{(33k^2+30k+1)}$,
$UP1 = \frac{(K+3)(k-1)^2}{16}$, $UP2 = k-1$, $UP3 = \frac{5(k-1)}{2}$,
$UP4 = \frac{k(k-1)(k+5)}{2(k+1)}$, $UP5 = 2(3k+1) - \sqrt{(13k^2+50k+1)}$, $UP6 = \frac{-k^4+12k^3+78k^2-92k+3}{8k^2-24k+80}$.

4. Compact Star Models

In order to validate the model, we examine our model with observational data. We have considered the pulsar 4U 1820-30 whose estimated mass and radius are $1.58M_{\odot}$ and 9.1 km (Gangopadhyay *et al.* (2013)). If we set these values for mass and radius then from equation (26) we obtain the value of $k = 3.1$ which is well inside the valid range for k. Similarly assuming masses of some well studied compact stars like PSR J1903+327, 4U 1608-52, Vela X-1, PSR J1614-2230, SMC X-4 and Cen X-3, we have obtained the same radius calculated by Gangopadhyay *et al.* (2013) for values of k in the valid range. The values of mass, radius, k and other relevant quantities like central density ρ_c, density at the boundary ρ_R, the compactification parameter u and $\frac{dp_r}{d\rho}$ at the centre for $p_0 = 1.08$, are shown in Table 3.

Table 3: Estimation of physical values based on observational data for $p_0 = 1.08$.

STAR	k	M ($M_{\odot}$)	R (Km)	ρ_c (MeV fm^{-3})	ρ_R (MeV fm^{-3})	$u(=\frac{M}{R})$	$\left(\frac{dp_r}{d\rho}\right)_{r=0}$
4U 1820-30	3.100	1.58	9.1	2290.97	277.12	0.256	0.206
PSR J1903+327	3.176	1.667	9.438	2129.82	257.62	0.261	0.199
4U 1608-52	3.458	1.74	9.31	2188.78	267.75	0.276	0.176
Vela X-1	3.407	1.77	9.56	2075.80	251.08	0.273	0.179
PSR J1614-2230	3.997	1.97	9.69	2020.48	244.39	0.300	0.144
SMC X-4	2.514	1.29	8.831	2432.67	294.25	0.215	0.285
Cen X-3	2.838	1.49	9.178	2252.20	272.42	0.239	0.235

In order to examine the nature of various physical quantities throughout the distribution, we have considered a particular star 4U 1820-30 for which mass $M = 1.58M_{\odot}$, radius $R = 9.1km$, the physical parameter $p_0 = 1.08$ and the geometric parameter $k = 3.1$. We have shown the variation

of density and pressures in Figure 2 and Figure 3, respectively. It is observed that the transverse pressure $p_\perp$ is less than the radial pressure for r in the range $0 < r < 2.78903$. Subsequently $p_\perp$ dominates p_r in the region $2.78903 < r \leq 9.1$. The radial pressure p_r vanishes at $r = 9.1$. In Figure 4, we have shown the variation of anisotropy throughout the distribution. The variations of sound speed in the radial and transverse directions are shown in Figure 5. From Figure 6, it is evident that the strong energy condition, $\rho - p_r - 2p_\perp \geq 0$ is satisfied throughout the distribution. Though we have not assumed any explicit expression for the EOS in our model, we have shown the nature of variation of pressures p_r and $p_\perp$ against density in Figure 7. For a relativistic model to be stable in its region of validity, we must have the adiabatic index $\Gamma > \frac{4}{3}$. The variation Γ against radius is shown in Figure 8. It is clear from Figure 8 that $\Gamma > \frac{4}{3}$ throughout the star. The variation of gravitational red shift, $z(r) = \sqrt{e^{-\nu(r)}} - 1$ in the radial direction is shown in Figure 9. It is easy to note that the red shift is monotonically decreasing function from the centre to boundary. Further, the red shift at the centre z_c and on the boundary z_R are both positive and finite.

5. Discussion

Spherical distribution of matter on pseudo-spheroidal spacetimes have been studied by a number of researchers in the recent past Tikekar and Thomas (1998); Tikekar (1999); Tikekar and Thomas (2005); Thomas *et al.* (2005); Thomas and Ratanpal (2007); Paul *et al.* (2011); Chattopadhyay and Paul (2010); Chattopadhyay *et al.* (2012). In this paper, we have obtained a new class of solutions to Einstein's field equations for a spherically symmetric anisotropic distribution of matter and have shown that our model can fit to the observational data of a number of well studied pulsars (Gangopadhyay *et al.* (2013)). On assuming a particular form of radial pressure and on the basis of elementary criteria for physical acceptability of a compact spherically symmetric distribution of matter, we have obtained the bounds for the physical as well as geometric parameters of the model. It is found that our model can accommodate a number of pulsars like 4U 1820-30, PSR J1903+327, 4U 1608-52, Vela X-1, PSR J1614-2230, SMC X-4 and Cen X-3. We also have studied, in detail, a particular pulsar 4U 1820-30, and have shown graphically the profile of different physical quantities throughout the distribution. In short, study of compact stars on the background of pseudo-spheroidal spacetime is highly interesting in the

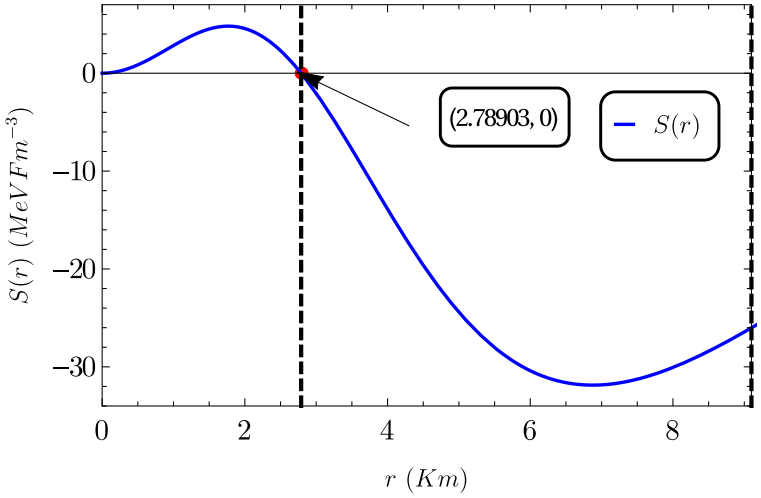

Fig. 4.— Anisotropy Vs Radius

sense that it generates models compatible with observational data and at the same time having a definite 3-space geometry, namely, pseudo-spheroidal geometry which many other spacetimes may not possess.
